Sir:

Enclosed herewith for filing is the patent application of inventors, RODNEY W. SALO, KENNETH LLOYD BAKER, and LAWRENCE S. BAUMANN, for "CARDIAC RHYTHM MANAGEMENT SYSTEM WITH OPTIMIZATIN OF CARDIAC PERFORMANCE USING HEART RATE" together with the following:

- (1) One copy of nine (9) sheets of patent drawings;
- (2) The Declaration, Power of Attorney and Petition unexecuted by the inventors;
- (3) The filing and recording fees are calculated as follows:

Basic filing fee	\$ 690.00
Total number of claims in excess of 20, times \$18.00 . . . . .	\$ 0
Number of independent claims, minus 3, times \$78.00 . . . . .	\$ 0
Surcharge fee (\$260.00) for filing of multiple dependent claim(s) . .	\$ 0
Recording fee for assignment	\$ 0
Total	\$ 690.00

A check in the amount of \$690.00 is enclosed to cover the filing and recording fees thereon.

The Commissioner is authorized to charge any fees or refund any overpayment under 37 C.F.R. 1.16 and 1.17 which may be required by this paper to Deposit Account No. 08-1265.

Yours very truly,

NIKOLAI, MERSEREAU & DIETZ, P.A.

**CARDIAC RHYTHM MANAGEMENT SYSTEM WITH  
OPTIMIZATION OF CARDIAC PERFORMANCE USING HEART RATE**

**Background of the Invention**

**I. Field of the Invention**

5        This invention relates generally to implantable cardiac rhythm management devices, and more particularly to a method for establishing an optimum pacing mode and delay parameters for multiple pacing sites in a dual chamber implantable programmable pacemaker.

**II. Related Art**

10        An earlier patent to Baumann, a co-inventor herein, Patent 4,800,471, assigned to the assignee of the present invention, the teachings of which are hereby incorporated by reference, explains that cardiac pacing can be used to  
15        improve hemodynamics in congestive heart failure (CHF) patients. One recognized and accepted indication of hemodynamic performance is reflected in the patient's pulse pressure (PP) which is defined as the difference between systolic aortic pressure and diastolic aortic  
20        pressure. PP could be used to optimize the pacing parameters in applying CHF therapy, however, this would require the use of a suitably positioned pressure sensor.

      The Baumann '471 patent recognizes that an indirect indication of PP can be derived from the patient's atrial  
25        cycle length (ACL), which is the duration of the interval between consecutive P-waves in an ECG signal. The earlier Baumann patent discloses a method for using ACL to optimize CHF therapy parameters that involves looking at a transient sequence in which, after a period of  
30        intrinsic cardiac activity, a short predetermined

sequence of pacing stimuli is delivered to the patient's heart. Any subsequent transient increase in measured ACL provides an indication of the therapy's effectiveness over intrinsic cardiac activity. Likewise, a subsequent  
5 transient decrease in measured ACL is indicative that the pacing therapy is non-beneficial.

In applying the methodology to an implantable, microprocessor-based controller of the type typically used in a programmable dual-chamber pacemaker, the device  
10 is made to cycle through transient paced beats with different pacing mode and AV delay configurations. Each such configuration is defined to be a group of consecutive beats with the same paced AV delay and the same pacing mode (right ventricular, left ventricular or  
15 biventricular pacing). Each of the configurations is immediately preceded by a group of baseline beats. In the disclosed arrangement, three different pacing modes and five different AV delays are used, with each such delay being shorter than a previously measured value of  
20 the intrinsic AV delay. The particular mode/AV delay combination that results in the largest increase in ACL is then programmed into the pacemaker to thereby optimize hemodynamic performance of the patient's heart. To avoid inaccuracies due to noise, the algorithm described in the  
25 Baumann '471 patent is made to vary the order of therapy; randomization and averaging techniques are then used to extract data from repeated tests.

While the above approach has proved to be a useful tool, it does not take into account variations in time  
30 between pulse events with respect to pacing at multiple

sites. It is common to stimulate both ventricle chambers, for example, and particularly the left ventricle can be provided with a plurality of sequentially paced sites. Each of these is operated  
5 using a timed delay sequence which may be selected from a menu of sequence timings which itself may change as data regarding patient history accumulates. Thus, if all paced sites could be integrated into an optimal pacing rhythm, additional benefit could be accorded the patient.

10

#### SUMMARY OF THE INVENTION

The foregoing features and advantages of the invention are achieved by providing an improved method for optimizing the inter-site delay and pacing mode configuration of an implanted, programmable pacemaker  
15 when treating CHF patients. The pacemaker involved is of the dual chamber type that includes an atrial sense circuit, a ventricular sense circuit and a pulse generator for applying cardiac stimulating pulses selectively to the right ventricular chamber, the left  
20 ventricular chamber or both chambers sequentially (biventricular pacing). A plurality of pacing sites may be located in a single chamber, usually the left ventricle, and these are also paced using a time variable delay sequence. The patient's intrinsic atrial  
25 depolarization events are tracked and from such events the ACL is measured over a first predetermined number of heartbeats,  $N_1$ , to establish a baseline value. At least one of the inter-site delay interval and the pacing mode

configuration is changed for a predetermined number of stimulated heartbeats,  $N_2$  and, again, the ACLs between successive paced beats is measured. These steps are repeated in iterative cycles until all of the

5 preprogrammed inter-site delay intervals and ventricular chamber options have been utilized. Subsequently, a comparison is made to determine which configuration of pacing mode and inter-site delay values resulted in the maximum increase ACL and those values are then programmed

10 into the pacemaker. In that maximum increase of ACL correlates with maximum increase of PP, hemodynamic performances are thereby optimized. Additional performance parameters may also be used to correlate to PP or other relevant indicators of cardiac performance,

15 these performance parameters include: ventricular volumes, blood flow velocity, total acoustic noise, and direct measurement of pressure.

As used herein, the terms "site-to-site delay" and "inter-site delay" mean the time interval between any

20 sequential pacing events in the same cardiac cycle regardless of whether they occur in different or the same chamber. Thus, AV, V-V,  $V_1$ - $V_2$  (same chamber), A-A etc. may be represented depending on the pacing configuration.

The optimization determination is first made with

25 the patient at rest to determine the most advantageous pacing mode. Thereafter, a one or more additional or periodic determinations can be implemented with the patient exercising or otherwise in an active state employing the technique to determine the optimum site-to-

30 site delays and enable dynamic site-to-site delays to be

implemented based on activity level. This empowers the system to implement dynamic site-to-site delays on its own based on an internal monitoring system.

#### DESCRIPTION OF THE DRAWINGS

5       The foregoing features, objects and advantages of the present invention will become apparent to those skilled in the art from the following detailed description of a preferred embodiment, especially when considered in conjunction with the accompanying drawings  
10   in which:

Figure 1 is a schematic block diagram of a dual chamber pacemaker incorporating a microprocessor-based controller for pacing at a plurality of sites in which the inter-site delay parameters are optimized in  
15   accordance with the algorithms disclosed herein;

Figure 2 is a schematic block diagram of the microprocessor-based controller incorporated into the pacemaker of Figure 1;

Figures 3A, 3B, 3C, 3D and 3E, when arranged as  
20   shown in Figure 3, illustrate a flow diagram for the optimization algorithm of the present invention;

Figure 4 is a representation of a series of baseline and paced beats useful in explaining the development of ACL features in accordance with a first algorithm;

25       Figure 5 is a drawing similar to Figure 4 for a second algorithm; and

Figure 6 is a plot of one dynamic delay v. cycle length relationship.

# DESCRIPTION OF THE PREFERRED EMBODIMENT

The present invention provides a method for establishing an optimum pacing mode and delay parameters for multiple pacing sites in a dual chamber implantable programmable pacemaker. The invention is described below in the context of utilizing atrial cycle length as the measured parameter for assessing the efficacy of the pacing mode and delay parameters. One skilled in the art will recognize that a variety of alternative performance parameters may be used to determine the efficacy of the pacing mode and pacing parameter. These performance parameters include ventricular volumes, blood flow velocity, total acoustic noise, and direct measurement of pressure.

These performance parameters may be assessed with a number of specific methods. That is, there are a many ways of assessing cardiac function including systolic function and/or diastolic function of a heart, that may be incorporated into an implantable microcontroller based cardiac pacemaker. Thus, for example, the cardiac function sensing circuit may measure intracardiac impedance variations due to the influx and outflow of blood from one of the ventricular chambers. This method is discussed in U.S. Pat. Nos. 4,686,987 and 4,674,518 to Salo, which are hereby incorporated by reference. Using this method it is possible to assess ventricular volume, stroke volume, cardiac output and derivatives of these parameters.

The cardiac function sense circuit may also comprise an accelerometer for measuring heart sounds or total

acoustic noise (TAN). The TAN corresponding to optimal mechanical timing of the heart may be measured using an implantable accelerometer as disclosed in U.S. Pat. No. 6,044,298 to Salo et al, hereby incorporated by  
5 reference. It is also contemplated that a micromachined piezoelectric pressure transducer may be mounted on the right or left ventricular pacing lead where it may measure right or left ventricular pressure parameters such as end-diastolic or end systolic pressure or  
10 derivatives of these pressures corresponding to ventricular contractility.

The cardiac function sense circuit may also comprise a Doppler flow meter having a flow sensor operatively positioned relative to the aorta or pulmonary artery for  
15 measuring peak aortic or pulmonic flow velocity from which measures that are directly correlated to stroke volume and cardiac output may be derived. Similar measurements may be made of mitral or tricuspid flow velocity.

20 Referring now to Figure 1 representing a preferred embodiment, there is shown enclosed by a dashed-line box 10, a cardiac rhythm management device, here depicted as a VDD bradycardia pacemaker 12, which is adapted to be operatively coupled to a patient's heart by means of a  
25 conventional pacing lead 14. In particular, an atrial sensing electrode disposed in the right atrium of the heart is coupled by a wire 16 in the lead 14 to an atrial sense amplifier 18. Similarly, a ventricular sensing electrode disposed in the right ventricle is connected by  
30 a wire 20 in the lead 14 to a ventricular sense amplifier

22 contained within the pacemaker 12. Thus, when the SA node in the right atrium depolarizes, the resulting signal is picked up by the atrial sense amplifier 18 and applied to a microprocessor-based controller 24 which will be more particularly described with the aid of Figure 2. Ventricular depolarization signals (R-waves) are likewise amplified by the ventricular sense amplifier 22 and applied as an input to the microprocessor-based controller 24.

The microprocessor-based controller 24 is connected in controlling relationship to a pulse generator 26 to cause a ventricular stimulating pulse to be applied, via conductor 28 in lead 14, to tissue located proximate the apex of the right ventricle (RV) to initiate ventricular depolarization that spreads as a wave across both the right and left ventricles. The pulse generator 26, under control of the microprocessor-based controller 24, can also be made to apply stimulating pulses over a wire 30 in lead 14 to stimulate the heart's left ventricle (LV). If the pacing mode calls for biventricular pacing, the pulse generator 26 is controlled by the microprocessor-based controller 24 to deliver stimulating pulses to sites in both the right and left ventricles (BV). In accordance with contemporary techniques, the left ventricle additionally may be sequentially paced at a plurality of locations (sites).

The microprocessor-based controller 30 controls the timing of stimulating pulses at cardiac sites relative to a selected preceding depolarization signal and to each other to thereby define site-to-site pulsing intervals.

The system is capable of pacing in several modes and at variable site-to-site time delays in each mode.

An external programmer 32 is arranged to send data signals transcutaneously to the implanted pacemaker 12 and also to receive signals originating within the pacemaker. In this fashion, a physician is capable of programming such parameters as pacing rate, pacing pulse width, pacing pulse amplitude, sensitivity, AV delay interval, etc., in a fashion known in the art. The external programmer may also be used to receive signals and pass them on to an external monitor (not shown) incorporating a microprocessor and associated memory.

Figure 2 shows a more detailed block diagram of the microprocessor-based controller 24 shown in Figure 1. It is conventional in its architecture and includes a microprocessor chip 34 and associated RAM and ROM memory modules 36 and 38 connected to it by an address bus 40 and a data bus 42. As is known in the art, the RAM memory 36 is a read/write memory comprising a plurality of addressable storage locations where multi-byte data words and operands used in the execution of one or more programs may be stored for subsequent readout. The ROM memory 38 will typically be used to store the control programs executable by the microprocessor chip 34.

Also connected to the address bus and data bus is an I/O interface module 44. If a separate analog-to-digital converter, as at 46, is utilized rather than an on-board A/D converter forming a part of the microprocessor chip 34, its output will be connected through the I/O module 44 allowing the analog outputs from the atrial sense

amplifier 18 and the ventricular sense amplifier 22 to be digitized before being routed to the microprocessor chip 34. If the particular microprocessor employed incorporates an on-board A/D converter (as is somewhat conventional), then the outputs from the A-sense amplifier 18 and V-sense amplifier 22 are applied directly to appropriate inputs of the microprocessor chip 34.

Also coupled to the I/O module 44 is a transceiver 48 that is used to interface the external programmer 32 to the implanted pacer 12. The manner in which an external programmer appropriately placed on the chest wall in proximity to the implanted device is capable of transmitting digitally encoded data therebetween is well known to those skilled in the pacemaker art.

Figures 3A, 3B, 3C, 3D and 3E when arranged as shown in Figure 3 comprise a flow chart of the algorithms executed by the microprocessor 34 in arriving at an optimal pacing mode and inter-site delay combination for a patient in which the system of the present invention is implanted.

Before explaining the steps of the algorithm in detail, a brief overview of the methodology is deemed helpful.

The algorithms can be executed by the microprocessor-based controller in the pacer or in an external microprocessor in the monitor/programmer 32. In the following description, it is assumed that the control algorithms are executed by the microprocessor 34 in the implanted device. The algorithms, using cardiac atrial

cycle lengths measured in the VDD pacemaker, determines a patient's optimum pacing mode and inter-site delay configuration, which is the mode (e.g., RV, LV, BV, RV and LV<sub>1</sub>, LV<sub>2</sub>, etc.) and inter-site delay during VDD pacing  
5 which maximizes cardiac function (e.g., PP) for the patient. The pulse generator 26 is then set to operate at this optimum pacing mode and inter-site delay.

The optimal pacing mode and associated optimum inter-site delays are determined from the maximum (or  
10 minimum) value of one of several empirically derived features which are calculated from the atrial cycle lengths. In particular, the atrial cycle lengths immediately following a transition from an intrinsic or paced baseline (BL) to a paced mode, inter-site delay,  
15 i.e., during a transient period of the paced mode and inter-site delay, is used. Thus, this invention eliminates the need for a period of waiting for hemodynamic stability to be reached during the paced mode and particular inter-site delay.

20 The pulse generator will be made to cycle through a predetermined number of intrinsic or paced BL beats followed immediately by paced beats using a first mode and inter-site delay configuration, followed immediately by additional intrinsic or paced BL beats, followed  
25 immediately by beats of a second mode and inter-site delay configuration, etc., until all of the possible programmed configurations have been utilized. The ACL between successive beats is computed and stored as an array in the RAM memory of the microprocessor-based  
30 controller.

Once the array of ACL values are stored, they are subsequently processed to arrive at values of ACL features. In particular, the array of values may be smoothed using a 3-point moving rectangle window or an  
5 11-point moving Blackman window. Then for each configuration and repeated instances thereof, further computations are made to identify the particular configuration exhibiting the largest average of the smoothed ACL features. It is this configuration that is  
10 determined to be the optimum and the pacemaker is then set to operate in this optimum configuration. The automatic selection of optimal mode delay which is found to optimize cardiac function eliminates any need for manual programming of the implanted pacemaker by the  
15 physician.

The algorithms of the present invention are based upon a hypothesis that if a transient change in atrial cycle length is large positive, then the transient change in aortic pulse pressure is also large positive. Thus,  
20 the largest positive change in atrial cycle length predicts the largest positive change in aortic pulse pressure.

There is a physiological basis for this relationship. A large, sudden increase in the aortic  
25 pressure (in this case due to the sudden change from baseline cardiac function to paced mode inter-site delay cardiac function) is sensed by arterial baroreceptors, and the reflex mechanism of the Autonomic Nervous System (ANS) tries to drive the aortic pressure back to its  
30 previous stable (in this case, baseline) value by

increasing the atrial cycle length. The ANS acts as a negative feedback control system for the aortic pressure.

The paced mode and inter-site delay associated with the largest mean increase in ACL is hypothesized to be  
5 the optimum paced mode and inter-site delay for the pacemaker. The optimum is the one that provides a maximum increase in aortic pressure over baseline aortic pressure for the then-current state of activity of the patient. As will also be seen, this may change with  
10 increased levels of activity in the patient.

With the foregoing summary in mind, then, attention is directed to the flow charts of Figures 3A through 3D. The first step in the algorithm is to derive a baseline. The pulse generator is initially inhibited while  
15 intrinsic cardiac activity is sensed such that a value of the patient's intrinsic AV delay and ACL can be measured. Next, the physician may generate a list of all possible combinations of three pacing modes and a predetermined number of inter-site delay values where each of the delay  
20 values is set as desired. While a different number of paced inter-site delay values can be selected, arbitrarily and for purposes of explanation of the inventive algorithm, it will be assumed that five different inter-site values are established by the  
25 physician. These may include a plurality of pacing sites in the same chamber and/or sites in several chambers. Generally, plural sites will be limited to the left ventricle, however. This leads to  $3 \times 5 = 15$  possible configurations as indicated in block 52.

To avoid any influence that the particular order in which the configurations are employed in pacing the patient, the list generated in step 52 is randomized as reflected in block 54 in Figure 3A.

5        Again, without limitation, a string of beats with the pulse generator inhibited may be used to establish BL and then for each of these baseline beats, the atrial cycle length between them is determined. As earlier mentioned, rather than using intrinsic inter-site delays  
10        to establish BL, the BL can also be at a particular configuration of pacing mode and inter-site delays. In the description to follow, a group of at least 15 sequential beats are generated. The ACL measurement may be performed in the microprocessor by initiating a timer  
15        upon the occurrence of a P-wave in the cardiac electrogram and stopping the timer upon detection of the next succeeding P-wave. The ACL value associated with each BL beat is then stored as an array in the RAM memory  
36.

20        Referring again to the block diagram of Figure 3A, immediately following the last of the beats used in establishing BL, the heart is paced using a selected configuration drawn from the randomized list developed at block 54. Again, without limitation, the second number  
25        of beats may equal five. As with the BL beats, the ACL for the paced beats is also determined as reflected in block 58.

A test is next made at block 60 to determine whether all of the 15 possible configurations on the randomized

list have been used and the ACL values associated therewith stored in the memory.

If not all of the configuration possibilities have been exhausted, control returns over path 61 to block 56  
5 and the operations reflected in blocks 56 and 58 are repeated until all of the possibilities have been exhausted. So that any anomalies which may have occurred in the measurement of the respective ACL values can be averaged out, steps 54, 56, 58 and 60 are repeated a  
10 predetermined number of times, e.g., five times, to obtain additional instances of the configurations that can later be averaged. See decision block 62.

The change in PP caused by the five paced beats in step 58 is immediate. There is no time delay. However,  
15 the change in ACL caused by the reflex mechanism of the Autonomic Nervous System in response to this change in PP is not immediate. There is a time delay of several beats. Thus, the delayed change in ACL can occur during the 15 BL beats in step 56 which follow the five paced  
20 beats in step 58. Thus, the final 15 or more BL beats in step 64 are needed to follow the final five paced beats in step 58.

Once the raw ACL values have been computed and stored as an array in the RAM memory, further algorithms  
25 may be used to process the raw data in arriving at the particular pacing mode-AV delay configuration yielding optimum hemodynamic performance.

Algorithm 2 shown on Figure 3C is executed to first select candidates for being the optimum configuration of  
30 pacing mode and inter-site delays. Here at block 77, the

raw ACL data (or VCL data) are first smoothed using a known signal processing approach referred to as an 11 point moving Blackman window which yields a smoothed ACL array, (sACL). At block 78, a determination is made as to whether any abnormal beats, e.g., PVCs, occurred during an interval from eight beats before the first transient pace beat to 8 beats after the last transient paced beat. If abnormal beats are detected, the collected data is defined to be an "invalid instance".

10 If no such abnormal beats occurred, it is defined to be a "valid instance". Next, and as reflected by block 79, for each configuration, a determination is made as to whether less than three "valid instances" occurred and, if so, it is defined to be an "invalid configuration".

15 On the other hand, if three or more valid instances occur, it is defined to be a "valid configuration".

Next, as indicated by block 80, for each valid instance of a valid configuration, a determination is made as to the maximum value of sACL values in an interval from two beats after the first beat of a configuration instance to eight beats after the first beat of the configuration instance. Likewise, a minimum value of sACL values in an interval from three beats before the first beat of the configuration instance to the beat with the maximum value is determined. Figure 5 is helpful in defining the respective intervals in which the maximum values and minimum values are to be found.

20 Once the maximum value and minimum value in the respective intervals have been determined, a smoothed ACL feature value, referred to in the flow charts by the

25

30

acronym sACLf, is computed as the maximum value minus the minimum value.

Upon completion of step 80, for each of the valid configurations of mode and inter-site delays, the mean of the sACLf values over the number of valid instances of a given configuration is computed. See block 82. Next, out of the previously determined valid configurations, the configuration exhibiting the largest mean sACLf is computed (block 84).

Once the particular configuration exhibiting the largest mean sACLf is determined, via step 84, the number of valid instances where the particular valid configuration has been repeated are examined to determine a median value and a maximum value of the smoothed ACL feature, sACLf. With the median and maximum values so determined, a test is made to determine whether the quantity  $(MAX/MEDIAN - 1)$  is less than a predefined threshold. The purpose of this threshold test is to remove a MAX whose value is too large (relative to the median value). The "predefined threshold" has been determined empirically from data accumulated from a significant number of patients as a value of 9.5, which gave good results for the set of patients investigated.

If the result of the test is true, a potential candidate for the optimum configuration has been found (block 88). However, if the test at block 86 had proved false, the instance with the maximum value of sACLf is defined to be an invalid instance. If this valid configuration now has less than three valid instances, then it is defined to be an invalid configuration. If

the valid configuration has three or more valid instances, the mean of values of valid instances are calculated for the valid configuration. Control then loops back over line 91 to block 84 to again repeat steps  
5 84 and 86 until such time as the test set out in block 86 comes out "true".

Referring again to the flow diagram of Figure 3A, after all candidates for the optimum configuration have been determined, further processing takes place to  
10 determine which of the candidates is the optimum configuration so that the pacemaker can be programmed to operate in this configuration. Specifically, a test is made at block 92 to determine whether the largest mean sACLF computed at block 82 is less than 8.1 milliseconds.  
15 If it is, algorithm 1 of Figure 3B is executed. If not, a further test is made to determine whether the largest mean sACLF value is greater than 29.0 milliseconds. If so, algorithm 3 illustrated at Figure 3D is executed. If the largest mean sACLF feature value lies between 8.1  
20 milliseconds and 29.0 milliseconds, it is the optimum configuration and, as indicated by block 96, the pacemaker is programmed to operate with that configuration of pacing mode and AV delay. The 8.1 ms and 29.0 ms values have been empirically established by  
25 study of data obtained from a set of ten patients in a study.

Referring next to Figure 3B, the details of Algorithm 1 will be further explained. The first step in Algorithm 1 is identified by block 66 and involves  
30 smoothing the array of ACLs with a 3-point moving

rectangle window. The resulting sACLf values are then also stored in the RAM memory. While other smoothing techniques are known to persons skilled in signal processing, a 3-point moving rectangle moving technique  
5 proves to be simple to execute and produces reliable results.

As was the case with algorithm 2, tests are made to determine whether any abnormal beats occurred in the interval from 8 beats before a first paced transient beat  
10 to 8 beats after the last paced transient beat for each of the configuration instances and if such an abnormal beat did occur, that configuration instance would be determined to be invalid. Then, each configuration is examined to determine if three or more valid instances  
15 were found in that configuration and, if so, it would be defined to be valid. However, if a configuration was found to include less than three valid instances, it would be defined as an invalid configuration.

Next, and as is reflected by block 68 in the flow  
20 diagram of Figure 3B, for each valid instance of each valid configuration, the maximum value and the minimum value of the smooth ACL in an interval from two beats after the first beat of the configuration instance to seven beats after the first beat of the configuration  
25 instance are computed. This operation is further explained with the aid of Figure 4. In Figure 4, there is shown a series of 15 baseline beats, followed by five paced beats of an instance of a first configuration identified as C, again followed by another series of 15  
30 baseline beats. The interval in which the maximum and

minimum values of smoothed ACLs are to be located is labeled "MAX and MIN". Likewise, the interval in the which the mean value of the smoothed ACLs is to be located is identified by "MEAN". By selecting the  
5 intervals in the manner indicated, changes in ACL of a transient nature as distinguished from steady state is guaranteed. Once the MAX and MIN values of sACL for the configuration instance are known, a test is made to determine whether the absolute value of the quantity (MAX  
10 - MEAN) is greater than the absolute value of the quantity (MIN - MEAN) for the configuration instance. If the outcome of the test is true, then the smoothed ACL feature (sACLf) for the configuration instance is determined to be the quantity (MAX - MEAN). If the test  
15 is false, then sACLf is made to be (MIN - MEAN). See steps 70 and 72 in block 68.

Next, as is indicated by operation block 74, for each of the valid configurations, a computation is made to determine the average or mean of the sACLf over the  
20 number of valid instances of that configuration. Once the operation indicated by block 74 has been completed, the particular valid configuration exhibiting the greatest mean of smoothed ACL features is identified, as the pacemaker is automatically programmed to operate with  
25 this optimum configuration. See block 76.

Referring again to Figure 3A, if the test at block 94 had established that the largest mean sACLf had been greater than 29.0 milliseconds, algorithm 3 shown in Figure 3D would have been executed rather than algorithm  
30 1. Referring to Figure 3D, the steps therein are

substantially identical to those of algorithm 2 shown in Figure 3C except that in block 97 of Figure 3D corresponding to block 80 in Figure 3C, the maximum value of sACL (or sVCL) is determined at an interval of from  
5 one beat after the first beat of a configuration instance rather than from two beats after a first beat configuration instance. Secondly, block 100 in algorithm 3 shown in Figure 3D differs from block 88 of algorithm 2 shown in Figure 3C in that rather than identifying a  
10 candidate optimum configuration, the actual optimum configuration is established and the pacemaker is then programmed to operate in this optimum configuration.

The above optimization is designed to be accomplished when the patient is asleep or otherwise in a  
15 sedentary state. The optimization algorithm, however, is also useful in optimizing pacing of the same individual during physical activities. This is illustrated in the flow diagram of Figure 3E which differs from Figure 3A only slightly. First, a determination is made at 49  
20 based on intrinsic ACL or VCL (indicative of HR) as to whether the patient is exercising or at rest after a number of intrinsic beats are sensed. If the rate exceeds a predetermined limit, it is presumed that the patient is exercising. If it is determined that the  
25 patient is exercising, the algorithm of Figure 3E is completed: otherwise the program ends at 50. The only difference in the determination in this situation is that the optimum pacing mode determined when the patient was at rest is retained and only the inter-site time delays  
30 are cycled and adjusted based on activity state. The

result obtained yields an optimum dynamic value of the inter-site delays.

In accordance with one aspect of the invention, and in addition to the above, it has been found that in bi-ventricular pacing dynamic inter-site delay adjustments may be made on a beat-by-beat basis based on a linear function of the VCL or ACL. This relationship may be represented by the relation:

$$\begin{aligned}d_{vv} &= mi_{vv} + b \\m &= \frac{d_{\max} - d_{\min}}{i_{lrl} - i_{url}} \\b &= d_{\max} - mi_{lrl}\end{aligned}$$

where

$i_{lrl}$  and  $i_{url}$  are the lower and upper rate limit intervals, the lower and upper rate limits having been set by the physician;

$d_{\max}$  and  $d_{\min}$  are the maximum and minimum interventricular delays for sequentially paced sites, one in each ventricle, which are also set by the physician based on the relative activity of the patient over time and which may be varied based on statistical activity trends of the patient;

$i_{vv}$  is the ACL (VCL could also be used);

$d_{vv}$  is the dynamic interventricular delay or the delay between sequentially paced sites, one in each ventricle.

In this manner, the  $d_{vv}$  inter-site delay can be caused to vary linearly with the ventricular cycle length

(or ACL). This is illustrated by the plot of Figure 6. Alternatively, it is contemplated that a non-linear function may be used.

Thus, in accordance with the invention, patient  
5 tests have shown that the relatively easy-to-measure  
atrial cycle length (or ventricular cycle length) can be  
used to automatically determine the pacing mode and site-  
to-site delay configuration which provides pulse  
pressures greater than the pulse pressure achieved with  
10 baseline cardiac performance. The need for a special  
sensor to actually measure pulse pressure itself, which  
is difficult to measure, is eliminated.

This invention has been described herein in  
considerable detail in order to comply with the patent  
15 statutes and to provide those skilled in the art with the  
information needed to apply the novel principles and to  
construct and use such specialized components as are  
required. However, it is to be understood that the  
invention can be carried out by specifically different  
20 equipment and devices, and that various modifications,  
both as to the equipment and operating procedures, can be  
accomplished without departing from the scope of the  
invention itself. As already mentioned, the intrinsic  
and paced beat information can readily be telemetered out  
25 to an external programmer/monitor incorporating a  
microprocessor and associated memory so that the ACL  
determinations and signal processing thereof can be done  
external to the patient in arriving at the optimal pacing  
mode-AV delay interval. Hence, the scope of the  
30 invention is to be determined from the appended claims.

-24-

## CLAIMS

What is claimed is:

1. A method of optimizing the pacing mode and inter-site delay configuration of a dual chamber  
5 pacemaker of the type having means for sensing atrial depolarization events, means for sensing ventricular depolarization events and means for applying cardiac stimulating pulses selectively to the right, left or both ventricular chambers at a plurality of sites at  
10 predetermined delay intervals following detection of atrial depolarization events, comprising the steps of:
  - (a) tracking a patient's intrinsic atrial depolarization events;
  - 15 (b) measuring the patient's atrial cycle length (ACL) between successive atrial depolarization events over a first predetermined number of heart beats,  $N_1$ , a first set of inter-site delay intervals and storing the measured ACLs as an array in a memory to establish a baseline  
20 value;
  - (c) changing at least one of one or more inter-site delay intervals and pacing mode configuration s for a second predetermined number of heart beats,  $N_2$ , less than the first predetermined  
25 number of heart beats by changing
    - (i) the delay interval of the pacemaker between successive sites from the baseline value to a different delay interval;
  - (d) measuring the patient's ACLs between successive  
30 atrial depolarization events over the second

predetermined number of heart beats and storing the measuring ACLs in the array in said memory;

(e) calculating and storing an ACL feature value obtained from the patient's atrial cycle length measured in steps (b) and (d);

(f) repeating steps (a)-(e) in iterative cycles over a range of inter-site delay intervals;

(g) after step (f) for each pacing mode inter-site delay configuration calculating the average of the ACL features over all of the occurrences of the configuration;

(h) determining the optimal configuration from among the averages determined in step (g); and

(i) setting the inter-site delays and pacing mode configuration of the pacemaker to the optimal inter-site delays and pacing mode configuration established in step (h).

2. The method of claim 1 wherein the ACL feature value is calculated by the steps of:

(j) smoothing the array of ACLs;

(k) determining from the smoothed array of ACLs a maximum value and a minimum value in a first predetermined interval measured in beats for each inter-site delay and pacing mode configuration;

(l) determining from the smoothed array a mean value of ACLs in a second predetermined interval measured in beats for each inter-site delay and pacing mode configuration;

- 5 (m) computing an absolute value of the difference between said maximum value and said mean value and computing an absolute value of the difference between said minimum value and said mean value;
- 10 (n) comparing the absolute value of the difference between the maximum value and the mean value with the absolute value of the difference between the minimum value and the mean value to determine which is the larger; and
- 15 (o) setting the ACL feature value to the difference between the maximum value and the mean value when the absolute value of that difference is greater than the absolute value of the difference between the minimum value and the mean value, and setting the ACL feature value to the difference between the minimum value and the mean value when the absolute value of the difference between the maximum value and the mean value is less than or equal to the absolute value of the difference between the minimum value and the mean value.
- 20

3. A method for optimizing delay intervals between pacing sites and pacing mode configuration of a programmable dual chamber cardiac pacemaker of the type having means for sensing atrial and ventricular depolarization events, including a microprocessor-based controller for using a plurality of sites for selectively stimulating the right, the left or both ventricular chambers with pacing pulses at predetermined delay

25

30

intervals following detection of atrial depolarization events, the microprocessor-based controller having means for determining atrial cycle lengths and a memory for storing data in an addressable array, comprising the

5 steps of:

- 10 (a) storing in the memory a listing of pacing mode and inter-site delay configurations, each such configuration specifying ventricular chamber(s) to be stimulated and inter-site delay intervals to be utilized;
- 15 (b) pacing the ventricular chamber(s) in accordance with a pacing mode inter-site delay configuration selected randomly from said listing for a first number of beats,  $N_1$ , following a second number of intrinsic beats,  $N_2$ , sufficient to establish a base line;
- 20 (c) repeating step (b) for each pacing mode and inter-site delay configuration contained in the listing;
- 25 (d) determining the ACL values between each of the  $N_1$  and  $N_2$  beats resulting from steps (b) and (c) and storing said ACL value in the addressable array in the memory;
- (e) repeating steps (b) through (d) a predetermined number of instances,  $N_3$ ;
- 30 (f) smoothing the array of ACLs;
- (g) determining for all  $N_3$  instances of each pacing mode and inter-site delay configuration the maximum value of the smoothed ACLs in a first interval beginning after a change to the first

number of beats  $N_1$  and ending after a change to the second number of beats,  $N_2$ , and a minimum value of the smoothed ACLs in a second interval beginning a predetermined number of beats prior to a change from the  $N_2$  beats to the  $N_1$  beats and ending with the beat associated with the maximum value;

(h) computing a smoothed ACL feature as the difference between the maximum value and the minimum value;

(i) calculating the mean value of the smoothed ACL features computed in step (h) over the  $N_3$  instances for each pacing mode inter-site delay configuration and determining the configuration yielding the largest mean value;

(j) determining among the  $N_3$  instances associated with the configuration yielding the largest mean value a median value and a maximum value of smoothed ACL features; and

(k) programming the pacemaker to the configuration determined in step (i) when the difference between the ratio of maximum value and the median value is less than a predetermined value.

4. The method of claim 3 and when the ratio of maximum value and the median value of smoothed ACL features is greater than or equal to the predetermined threshold value, repeating steps (i) and (j) after recalculating the mean of the instances of the configuration associated with the largest mean value of

smoothed ACL features after removing the instance having the maximum value of smoothed ACL features from the instances.

- 5        5.    A method of optimizing the inter-site delay and  
pacing mode configuration of a dual chamber pacemaker of  
the type having means for sensing atrial depolarization  
events, means for sensing ventricular depolarization  
events and means for applying cardiac stimulating pulses  
selectively to a plurality of sites at locations selected  
10    the right, left or both ventricular chambers at  
predetermined inter-site delay intervals following  
detection of atrial depolarization events, comprising the  
steps of:
- 15        (a)   tracking a patient's intrinsic ventricular  
depolarization events;
  - (b)   measuring the patient's ventricular cycle  
length (VCL) between successive ventricular  
depolarization events over a first  
predetermined number of heart beats,  $N_1$ , and  
20        storing the measured VCLs as an array in a  
memory to establish a baseline value;
  - (c)   changing at least one delay interval and pacing  
mode configuration by changing, for a second  
predetermined number of heart beats,  $N_2$ , less  
25        than the first predetermined number of heart  
beats,
    - (i)   one or more inter-site delay intervals of  
the pacemaker from the baseline value to a  
different delay interval;

- (ii) the sites to which the stimulating pulses are applied;
  - (d) measuring the patient's VCLs between successive ventricular depolarization events over the second predetermined number of heart beats and storing the measured VCLs in the array in said memory;
  - (e) calculating and storing a VCL feature value obtained from the patient's ventricular cycle length measured in steps (b) and (d);
  - (f) repeating steps (a)-(e) in iterative cycles over a range of inter-site delay intervals and ventricular chamber(s) selected for receiving the cardiac stimulating pulses;
  - (g) after step (f) for each pacing mode inter-site delay configuration calculating the average of the VCL features over all of the occurrences of the configuration;
  - (h) determining the optimal configuration from among the averages determined in step (g); and
  - (i) setting the inter-site delay and pacing mode configuration of the pacemaker to the optimal inter-site delay and pacing mode configuration established in step (h).
6. The method of claim 5 wherein the VCL feature value is calculated by the steps of:
- (j) smoothing the array of VCLs;
  - (k) determining from the smoothed array of VCLs a maximum value and a minimum value in a first predetermined interval measured in beats for

each inter-site delay and pacing mode configuration;

- 5 (l) determining from the smoothed array a mean value of VCLs in a second predetermined interval measured in beats for each inter-site delay and pacing mode configuration;
- (m) computing an absolute value of the difference between said maximum value and said mean value and computing an absolute value of the  
10 difference between said minimum value and said mean value;
- (n) comparing the absolute value of the difference between the maximum value and the mean value with the absolute value of the difference  
15 between the minimum value and the mean value to determine which is the larger; and
- (o) setting the VCL feature value to the difference between the maximum value and the mean value when the absolute value of that difference is  
20 greater than the absolute value of the difference between the minimum value and the mean value, and setting the VCL feature value to the difference between the minimum value and the mean value when the absolute value of the  
25 difference between the maximum value and the mean value is less than or equal to the absolute value of the difference between the minimum value and the mean value.

7. A method for optimizing inter-site delay  
30 intervals and pacing mode configuration of a

programmable, dual-chamber, cardiac pacemaker of the type having means for sensing atrial and ventricular depolarization events, including a microprocessor-based controller using a plurality of pacing sites for  
5 selectively stimulating the right, the left or both ventricular chambers with pacing pulses at predetermined inter-site delay intervals following detection of atrial depolarization events, the microprocessor-based controller having means for determining ventricular cycle  
10 lengths (VCLs) and a memory for storing data in an addressable array, comprising the steps of:

- (a) storing in the memory a listing of pacing mode and inter-site delay configurations, each such configuration specifying ventricular chamber(s)  
15 to be stimulated and an inter-site delay interval to be utilized;
- (b) pacing the ventricular chamber(s) in accordance with a pacing mode inter-site delay configuration selected randomly from said  
20 listing for a first number of beats,  $N_1$ , following a second number of intrinsic beats,  $N_2$ , sufficient to establish a baseline;
- (c) repeating step (b) for each pacing mode and AV delay configuration contained in the listing;
- 25 (d) determining the VCL values between each of the  $N_1$  and  $N_2$  beats resulting from steps (b) and (c) and storing said VCL value in the addressable array in the memory;
- (e) repeating steps (b) through (d) a predetermined  
30 number of instances,  $N_3$ ;

- (f) smoothing the array of VCLs;
- (g) determining for all  $N_3$  instances of each pacing mode and inter-site delay configuration the maximum value of the smoothed VCLs in a first interval beginning after a change to the first number of beats,  $N_1$ , and ending after a change to the second number of beats,  $N_2$ , and a minimum value of the smoothed VCLs in a second interval beginning a predetermined number of beats prior to a change from the  $N_2$  beats to the  $N_1$  beats and ending with the beat associated with the maximum value;
- (h) computing a smoothed VCL feature as the difference between the maximum value and the minimum value;
- (i) calculating the mean value of the smoothed VCL features computed in step (h) over the  $N_3$  instances for each pacing mode inter-site delay configuration and determining the configuration yielding the largest mean value;
- (j) determining among the  $N_3$  instances associated with the configuration yielding the largest mean value a median value and a maximum value of smoothed VCL feature; and
- (k) programming the pacemaker to the configuration determined in step (i) when the difference between the ratio of maximum value and the minimum value is less than a predetermined value.

8. The method of claim 7 and when the ratio of maximum value and the median value of smoothed VCL features is greater than or equal to the predetermined threshold value, repeating steps (i) and (j) after  
5 recalculating the mean of the instances of the configuration associated with the largest mean value of smoothed VCL features after removing the instance having the maximum value of smoothed VCL features from the instances.

10 9. A method for optimizing inter-site delay intervals and pacing mode configuration of a programmable, dual-chamber, cardiac pacemaker of the type having means for sensing atrial and ventricular depolarization events, including a microprocessor-based  
15 controller using a plurality of pacing sites for selectively stimulating the right and left ventricular chambers with pacing pulses at predetermined inter-site delay intervals following detection of atrial depolarization events, the microprocessor-based  
20 controller having means for determining atrial cycle lengths (ACLs) or ventricular cycle lengths (VCLs) and a memory for storing data in an addressable array, comprising the steps of:

- 25 (a) establishing an upper rate limit and a lower rate limit for pacing and storing these in memory;
- (b) establishing a range of allowable delay intervals between pacing the right ventricle and pacing a first site in the left ventricle

in relation to said upper rate limit and said lower rate limit; and

- (c) making dynamic inter-site delay interval adjustments to optimize the interval based on a linear relationship between the delay interval between adjacent pulses in the right and left ventricles and the VCL or ACL, wherein said inter-site delay interval is adjusted between maximum and minimum values in said range of allowable delay intervals.

10. The method according to claim 9 wherein said adjustments are made on an on-going basis.

11. A method for optimizing atrioventricular delay, comprising:

- (a) tracking an intrinsic performance parameter of patient's heart;
- (b) measuring a performance parameter over a first predetermined number of heart beats,  $N_1$ , a first set of inter-site delay intervals and storing the measured performance parameter as an array in a memory to establish a baseline value;
- (c) changing at least one of one or more inter-site delay intervals and pacing mode configuration for a second predetermined number of heart beats,  $N_2$ , less than the first predetermined number of heart beats by charging

- (i) the delay interval of the pacemaker  
between successive sites from the baseline  
value to a different delay interval;
- (d) measuring the patient's performance parameter  
5 between successive atrial depolarization events  
over the second predetermined number of heart  
beats and storing the measuring performance  
parameter in the array in said memory;
- (e) calculating and storing an performance  
10 parameter feature value obtained from the  
patient's performance parameter measured in  
steps (b) and (d);
- (f) repeating steps (a)-(e) in iterative cycles  
over a range of inter-site delay intervals;
- (g) after step (e) for each pacing mode inter-site  
15 delay configuration calculating the average of  
the performance parameter features over all of  
the occurrences of the configuration;
- (h) determining the optimal configuration from  
20 among the averages determined in step (f); and
- (i) setting the inter-site delays and pacing mode  
configuration of the pacemaker to the optimal  
inter-site delays and pacing mode configuration  
established in step (g).

25 12. A method, as in Claim 11, wherein the performance  
parameter is selected from the group consisting of  
ventricular volumes, blood flow velocity, total acoustic  
noise, and direct measurement of pressure..

**CARDIAC RHYTHM MANAGEMENT SYSTEM WITH  
OPTIMIZATION OF CARDIAC PERFORMANCE USING HEART RATE**

**Abstract of the Disclosure**

A cardiac rhythm management device includes a dual  
5 chamber pacemaker, especially designed for treating  
congestive heart failure by pacing a plurality of sites.  
The device incorporates a program microcontroller which  
is operative to adjust the pacing mode and inter-site  
delay of the pacemaker so as to achieve optimum  
10 hemodynamic performance. Atrial cycle lengths measured  
during transient (immediate) time intervals following a  
change in the mode inter-site delay are signal processed  
and a determination can then be made as to which  
particular configuration yields the optimum performance.  
15 Performance is optimized when the patient is at rest and  
when the patient exercises so that a rate-adapted dynamic  
value of the optimum performance can be applied.

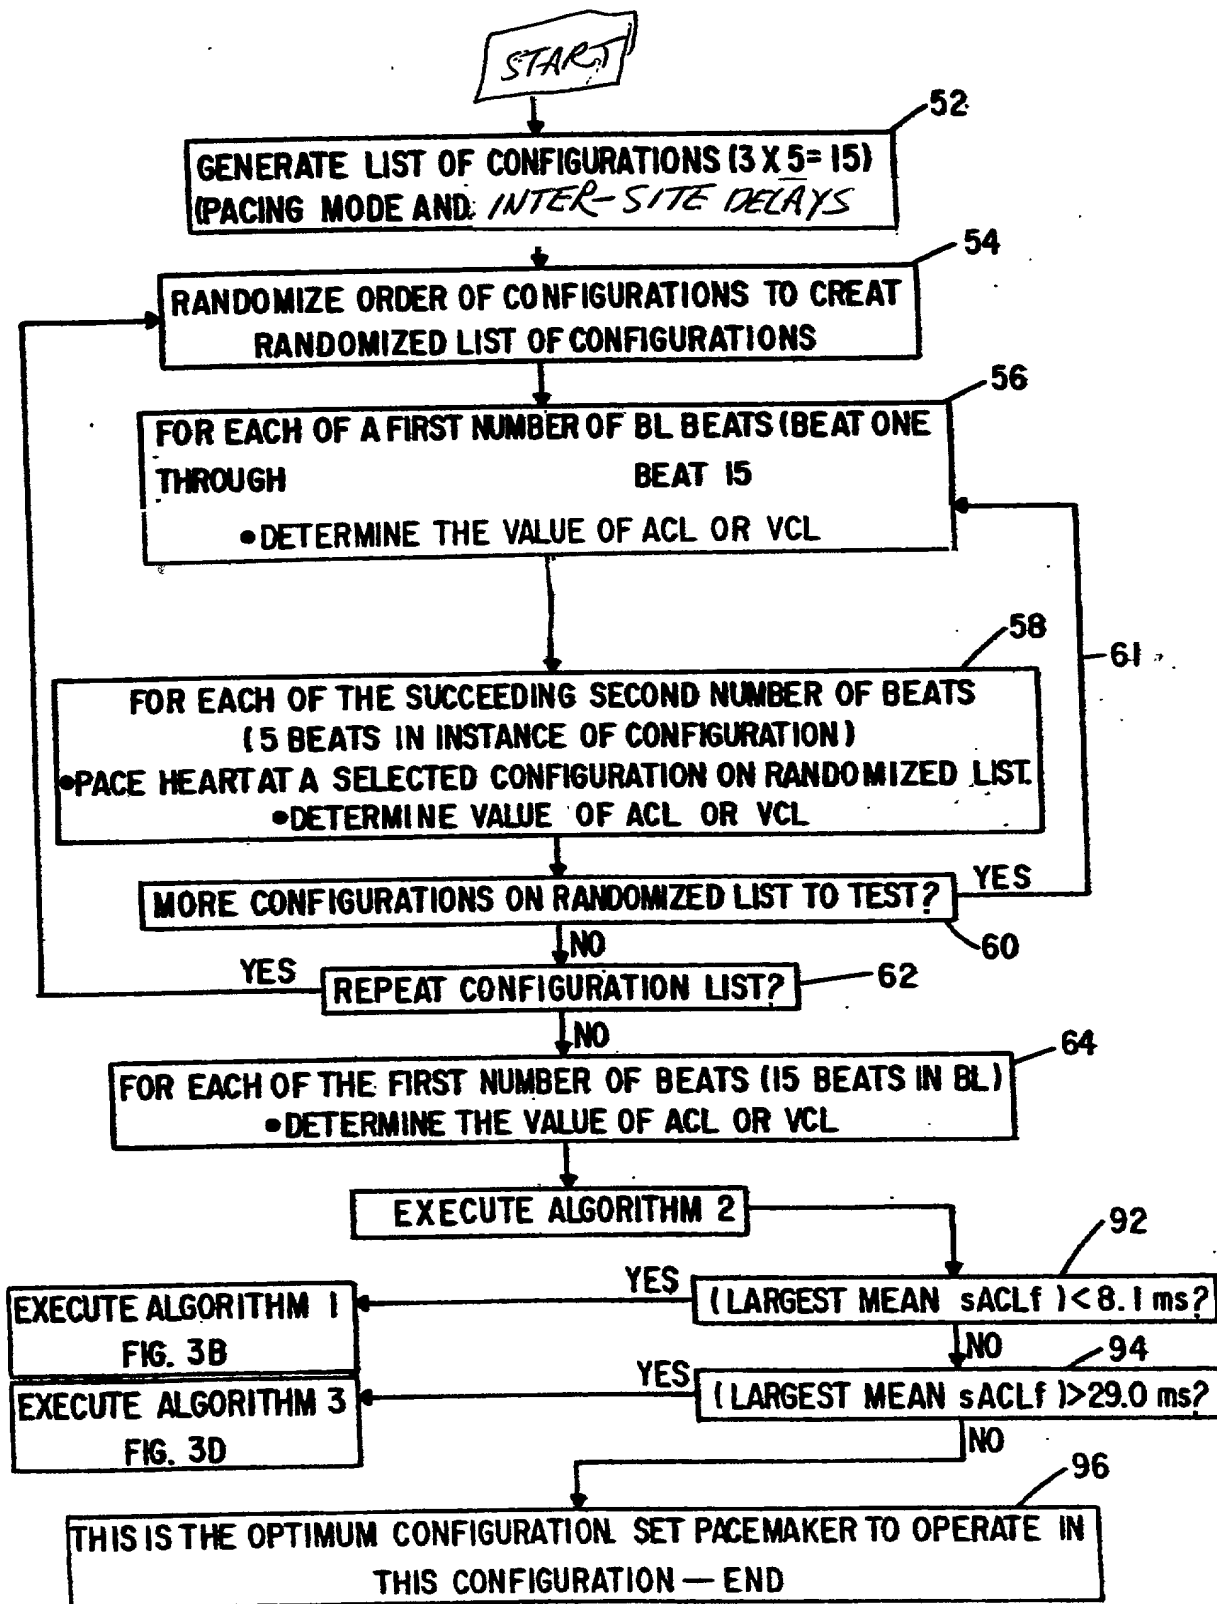

FIG. 3A

ALGORITHM 1

SMOOTH THE ARRAY OF ACLs OR VCLs WITH 3 POINT MOVING RECTANGLE WINDOW TO CREATE SMOOTHED ARRAY: sACL OR sVCL

FOR EACH CONFIGURATION INSTANCE:  
IF ANY ABNORMAL BEATS (PVC, ETC.) FROM 8 BEATS BEFORE FIRST PACED BEAT TO 8 BEATS AFTER LAST PACED BEAT, THEN THIS IS DEFINED TO BE AN INVALID INSTANCE.  
ELSE THIS IS DEFINED TO BE A VALID INSTANCE.

FOR EACH CONFIGURATION:  
IF LESS THAN 3 VALID INSTANCES THEN THIS IS DEFINED TO BE AN INVALID CONFIGURATION. ELSE THIS IS DEFINED TO BE A VALID CONFIGURATION.

FOR EACH VALID CONFIGURATION VALID INSTANCE:

- DETERMINE MAX. VALUE AND MIN. VALUE OF sACL OR sVCL IN INTERVAL FROM 2 BEATS AFTER FIRST BEAT OF CONFIGURATION INSTANCE TO 7 BEATS AFTER FIRST BEAT OF CONFIGURATION INSTANCE.
- DETERMINE MEAN VALUE OF sACL OR sVCL IN INTERVAL FROM 2 BEATS BEFORE FIRST BEAT OF CONFIGURATION INSTANCE TO 2 BEATS AFTER FIRST BEAT OF CONFIGURATION INSTANCE.
- DETERMINE sACL OR sVCL FEATURE VALUE sACLf OR sVCLf: IS MAGNITUDE (MAX.-MEAN) > MAGNITUDE (MIN.-MEAN)?  
YES: sACLf OR sVCLf = (MAX.-MEAN) — 70  
NO: sACLf OR sVCLf = (MIN.-MEAN) — 72

FOR EACH OF THE VALID CONFIGURATIONS:

- DETERMINE MEAN OF sACLf OR sVCLf OVER THE VALID INSTANCES OF THE CONFIGURATION.

AMONG THE VALID CONFIGURATIONS:

- DETERMINE THE CONFIGURATION WITH LARGEST MEAN OF sACLf OR sVCLf.

THIS CONFIGURATION IS THE OPTIMUM CONFIGURATION. SET PACEMAKER TO OPERATE IN THIS OPTIMUM CONFIGURATION.

[illegible]

ALGORITHM 3

SMOOTH THE ARRAY OF ACLs OR VCLs WITH 11 POINT MOVING BLACKMAN WINDOW TO CREATE SMOOTHED ARRAY: sACL OR sVCL

FOR EACH CONFIGURATION INSTANCE:  
IF ANY ABNORMAL BEATS (PVC, ETC.) FROM 8 BEATS BEFORE FIRST PACED BEAT TO 8 BEATS AFTER LAST PACED BEAT, THEN THIS IS DEFINED TO BE AN INVALID INSTANCE, ELSE THIS IS DEFINED TO BE A VALID INSTANCE.

FOR EACH CONFIGURATION:  
IF LESS THAN 3 VALID INSTANCES THEN THIS IS DEFINED TO BE AN INVALID CONFIGURATION, ELSE THIS IS DEFINED TO BE A VALID CONFIGURATION.

FOR EACH VALID CONFIGURATION VALID INSTANCE:

- DETERMINE MAX. VALUE OF sACL OR sVCL IN INTERVAL FROM 1 BEAT AFTER FIRST BEAT OF CONFIGURATION INSTANCE. TO 8 BEATS AFTER FIRST BEAT OF CONFIGURATION INSTANCE.
- DETERMINE MIN. VALUE OF sACL OR sVCL IN INTERVAL FROM 3 BEATS BEFORE FIRST BEAT OF CONFIGURATION INSTANCE TO BEAT WITH MAX. VALUE.
- DETERMINE sACL OR sVCL FEATURE VALUE sACLf OR sVCLf:  $sACLf \text{ OR } sVCLf = \text{MAX.} - \text{MIN.}$

FOR EACH OF THE VALID CONFIGURATIONS:

- DETERMINE MEAN OF sACLf OR sVCLf OVER THE VALID INSTANCES.

AMONG THE VALID CONFIGURATIONS:

- DETERMINE CONFIGURATION WITH LARGEST MEAN sACLf OR sVCLf.

AMONG THE VALID INSTANCES OF THIS VALID CONFIGURATION:

- DETERMINE MEDIAN VALUE OF sACLf OR sVCLf.
- DETERMINE MAX. VALUE OF sACLf OR sVCLf. IS  $(\text{MAX.} / \text{MEDIAN} - 1) < \text{PREDEFINED THRESHOLD}$ ?

YES

THIS IS THE OPTIMUM CONFIGURATION. SET PACEMAKE TO OPERATE IN THIS CONFIGURATION.

ATTORNEY FILE NO. 980457.ORI

**DECLARATION, POWER OF ATTORNEY, AND PETITION**

As below named inventors, we hereby declare that: our residences, post office addresses and citizenships are as stated below next to our names; that we verily believe we are the original, first and joint inventors of the subject matter which is claimed and for which a patent is sought on the invention entitled "CARDIAC RHYTHM MANAGEMENT SYSTEM WITH OPTIMIZATION OF CARDIAC PERFORMANCE USING HEART RATE", the specification of which is attached hereto.

We hereby state that we have reviewed and understand the contents of the specification including the claims as amended by any amendment specifically referred to in the Oath or Declaration.

We acknowledge the duty to disclose information which is material to patentability in accordance with Title 37, Code of Federal Regulations, Section 1.56.

We hereby appoint NIKOLAI, MERSEREAU & DIETZ, P.A., a professional association, consisting of the following attorneys/agents and the following attorneys/agents individually: Thomas J. Nikolai, Registration No. 19,283, Charles G. Mersereau, Registration No. 26,205, Paul T. Dietz, Registration No. 38,858, Steven E. Kahm, Registration No. 30,860, Kimberly S. Zillig, Registration No. P46,346 and Kevin W. Cyr, Registration No. 40,976 of 820 International Centre, 900 Second Avenue South, Minneapolis, Minnesota 55402-3325; Telephone No. (612) 339-7461, and hereby appoints the following attorneys/agents individually: Richard R. Clapp, Registration No. 31,751 and Tyler L. Nasiedlak, Registration No. 40,099 of 4100 N. Hamline Avenue, St. Paul, Minnesota 55112-5798; Telephone No. (651) 638-4000 our attorneys/agents with full power of substitution and revocation to prosecute this application and transact all business in the Patent and Trademark Office connected herewith.

Please direct all telephone calls and correspondence to: C. G. Mersereau, Esq. at  
NIKOLAI, MERSEREAU & DIETZ, P.A., 820 International Centre, 900 Second Avenue  
South, Minneapolis, Minnesota 55402-3325.

We hereby declare that all statements made herein of our own knowledge are true  
and that all statements made on information and belief are believed to be true; and further  
that these statements were made with the knowledge that willful false statements and the  
like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title  
18 of the United States Code and that such willful false statements may jeopardize the  
validity of the application or any patent issued thereon.
